Start Date: FY11

Expected Duration: FY13

Long-term Goal: To maintain effectiveness of backwater habitats.

Conservation Measures: BONY5, RASU6.

Location: Various off-channel fish grow-out ponds and native fish refugia.

Purpose: To determine best management practices for maintaining ample food resources for native fishes in off-channel ponds within the Colorado River floodplain.

Connections with Other Work Tasks (past and future): This work is related to B7, B11, C25, C34, F5, and G3.

Project Description: This three-year study will evaluate means to enhance food resources in the various flood-plain ponds being used within the LCR to hold or rear RASU and/or BONY. Off-channel habitats, including both man-made and natural flood-plain ponds are being used to support communities of RASU and BONY. In some ponds the fish are fed prepared feeds, in some cases the ponds are only fertilized with the assumption that this act boosts development of zooplankton for food, and in some cases neither feed nor fertilizer are added to the ponds and the fish must subsist on whatever food is naturally available. To successfully manage these habitats, the amounts of zooplankton in these ponds must be optimized. This study evaluates ways to manipulate zooplankton communities to benefit native fishes and works toward developing recommendations for adding feed and/or fertilization to maintain food levels needed by native fish to attain targeted growth rates.

Previous Activities: Information characterizing the zooplankton communities of 33 separate native fish ponds was collected quarterly during FY09 and FY10. This information was gathered through C34, and will be used as a baseline for comparison. At the start of FY11 an extensive literature search was performed to gather information on potential methods for boosting plankton production within fish rearing ponds. Information gathered from this search indicated that a mix of organic and inorganic

fertilizers was likely the best method for promoting the desired plankton bloom. Fertilizer quantities and types were selected based on recommendations from the reviewed literature and on the total surface area of the four individual ponds selected. Ponds were fertilized by two different methods, with two of the study ponds receiving inorganic ammonia phosphate and organic alfalfa pellet, and two of the ponds receiving ammonia phosphate and rice bran. A single pond received no fertilizer inputs and acted as a control. Plankton sampling was conducted prior to pond fertilization and then once a month from March through October. Data sets for all ponds were summarized and interpreted.

FY13 Accomplishments: Phytoplankton and zooplankton samples were collected and analyzed on a monthly or quarterly basis depending on the individual site. Results indicated that there was high variability across study sites, but that no clear relationship could be found between fertilization and increases of zooplankton biomass. In addition, there was no indication of an interaction between Backwater and Year, and biomass did not significantly vary over time. Thus, increased fertilization over time did not significantly increase total zooplankton biomass. Although there may have been weaknesses in this study in detecting immediate responses of fertilizer treatments because of sampling intervals, the overall variation recorded indicates that much more intense sampling would have been required to detect small differences if any. Because this variation in zooplankton biomass is likely more attributable to site-specific variables, it is expected that fertilizing backwaters may have little value in terms of increasing production.

FY14 Activities: Closed in FY13.

Proposed FY15 Activities: Closed in FY13.

Pertinent Reports: A three-year project report is being finalized and will be posted to the website when available.
